Our major research interest is the molecular mechanisms of higher brain functions in mammals such as emotion, and learning and memory. We are especially focusing on the roles of functional molecules localized in synapses, for instance, neurotransmitter receptors, signal transduction molecules and adhesion molecules, in neuronal information processing. We are examining receptor functions, synaptic transmission and plasticity, and their roles in whole animals with electrophysiological, biochemical, molecular genetic and behavioral approaches.

1. NMDA receptor phosphorylation and synaptic plasticity

Shoji Komai1, Takanobu Nakazawa2, Tohru Tezuka2, Tadashi Yamamoto2, and Toshiya Manabe: 1Division of Cell Biology and Neurophysiology, Department of Neuroscience, Faculty of Medicine, Kobe University, and 2Division of Oncology, Department of Cancer Biology

In the hippocampus, excitatory synaptic transmission is regulated dynamically depending on the pattern of synaptic activation: high-frequency activation induces long-lasting enhancement of synaptic efficacy referred to as long-term potentiation (LTP), and prolonged lower-frequency activation causes long-term depression (LTD) of synaptic transmission. Excitatory synaptic transmission is mediated by glutamate receptors and the N-methyl-D-aspartate (NMDA) receptor, one of the glutamate receptor subtypes, plays crucial roles in LTP and LTD induction.

Tyrosine phosphorylation of NMDA receptors by Src-family tyrosine kinases such as Fyn is implicated in synaptic plasticity. We identified Fyn-mediated phosphorylation sites on the GluR2 (NR2B) subunit of NMDA receptors. Seven out of 25 tyrosine residues in the C-terminal cytoplasmic region of GluR2 were phosphorylated by Fyn in vitro. Of these seven residues, Tyr1252, Tyr1336, and Tyr1472 in GluR2 were phosphorylated in human embryonic kidney fibroblasts when co-expressed with active Fyn, and Tyr1472 was the major phosphorylation site in this system. We then generated rabbit polyclonal antibodies specific to Tyr1472-phosphorylated GluR2, and showed that Tyr1472 of GluR2 was indeed phosphorylated in murine brain using the antibodies. Importantly, Tyr1472 phosphorylation was greatly reduced in fyn-mutant mice. Moreover, Tyr1472 phosphorylation grew evident when mice reached the age when hippocampal LTP started to be observed and its magnitude became larger. Finally, Tyr1472 phosphorylation was significantly enhanced after the induction of LTP in the hippocampal CA1 region. These data suggest that Tyr1472 phosphorylation of GluR2 is important for synaptic plasticity.

2. Adhesion molecules and synaptic plasticity

Kazuhiro Nakamura3, Yuji Kiyama, Toshitaka Nabeshima4, Masahiko Watanabe5, Masayoshi Mishina3, and Toshiya Manabe: 3Department of Molecular Neurobiology and Pharmacology, Graduate School of Medicine, University of Tokyo, 4Department of Neuropsychopharmacology and Hospital Pharmacy, Nagoya University School of Medicine, and 5Department of Anatomy, Hokkaido University School of Medicine

Adhesion molecules play critical roles in synaptic transmission and plasticity and we have examined functions of several kinds of adhesion molecules and their anchoring proteins. Telencephalin (TLCN) is a cell adhesion molecule selectively expressed in the telencephalon of the mammalian brain. The mutant mice lacking TLCN had no detectable abnormalities
3. Intracellular calcium regulation and synaptic plasticity

Misa Shimuta, Masahiko Watanabe, Hiroshi Takeshima, and Toshiya Manabe

The concentration of intracellular calcium is controlled by many kinds of molecules including ryanodine receptors (RyRs) and inositol triphosphate receptors. The precise function of RyRs in synaptic transmission is unknown, while three of their subtypes are expressed in the brain. We examined the role of RyRs in excitatory synaptic transmission in hippocampal slices, using type 3 RyR (RyR3)-deficient mice. The α-amino-3-hydroxy-5-methyl-4-isoxozolepropionic acid (AMPA) receptor-mediated basal synaptic responses in the CA1 region of mutant mice were smaller than those of wild-type mice, while there was no difference in NMDA receptor-mediated responses, suggesting selective postsynaptic modification of AMPA receptors by RyR3. The expression of synaptic AMPA receptors examined by Western blotting or immunohistochemistry was indistinguishable, suggesting that the smaller AMPA synaptic responses in mutant mice were not due to the reduced number of synaptic AMPA receptors. Although the initial potentiation was similar, LTP was smaller in mutant mice. There were no differences in presynaptic electrophysiological properties. We conclude that RyR3 regulates the properties of AMPA receptors postsynaptically.

4. Regulation of synaptic glutamate concentrations and synaptic plasticity

Hiroyuki Katagiri, Kohichi Tanaka, and Toshiya Manabe

At the excitatory synapse, the neurotransmitter glutamate released from the presynaptic terminal is subject to the reuptake by glial or neuronal glutamate transporters. Although glutamate transporters maintain low extracellular levels of glutamate in the nervous system, little is known about their roles in synaptic plasticity. Here, using knockout mice lacking GLT-1 that is the most abundant glial subtype of glutamate transporters, we showed that LTP induced by tetanic stimulation in mutant mice was impaired in the hippocampal CA1 region. When tetanic stimulation was applied in the presence of low concentrations of an NMDA receptor antagonist, the impairment was overcome. Consistent with these results, the increased glutamate in the synaptic cleft of mutant mice preferentially activated NMDA receptors. Furthermore, analyses of mutant mice revealed that the magnitude of NMDA receptor-dependent transient synaptic potentiation during low-frequency stimulation depended on the concentration of glutamate in the synaptic cleft. These findings suggest that GLT-1 plays critical roles in LTP induction, as well as in short-term potentiation, through regulation of extracellular levels of glutamate, which enables appropriate NMDA receptor activation.

5. Analysis of muscarinic acetylcholine receptor functions using knockout mice

Minoru Matsui, Fumiko Arima, Toru Shino, Yuji Kiyama, Ayako M. Watabe, and Toshiya Manabe

We are investigating the biological function of muscarinic acetylcholine receptors (mAChRs) using mutant mice lacking corresponding genes. These mice have been established by Matsui et al. in the Laboratory of Biomedical Genetics, Graduate School of Pharmaceutical Sciences, University of Tokyo (Prof. Makoto Mark Taketo’s Lab.).

The mAChR belongs to a group of seven transmembrane-spanning receptors and is distributed widely in both central and peripheral nervous systems. Five distinct genes for mAChRs were cloned in rats and humans. Now, it is generally accepted that five classes of affinity (M₁, M₂, M₃, M₄, and M₅) defined by various muscarinic ligands are attributable to these gene products, respectively. Previously, Matsui et al. have cloned the all five genes for mouse mAChRs (Chrm1, Chrm2, Chrm3, Chrm4, and Chrm5), and determined the chromosomal locations of these genes.

Elucidation of the subtype-specific functions of mAChRs has been a matter of considerable interest because they are suitable targets for various therapeutic drugs. However, due to poor subtype selectivity of the available ligands, pharmacological attempts to elucidate the role of each subtype remain inconclusive. As an alternative and more powerful
strategy, we are studying the receptor function using our knockout mice for M₁, M₂, M₃, M₄, and M₅. In order to minimize the contaminating effects caused by different genetic backgrounds, we are carefully backcrossing these animals to C57BL/6J and DBA/2J strains. We have previously reported that the M₃ knockout mice are retarded in post-weaning growth and devoid of pilocarpine-induced salivation. The mice also showed partial mydriasis, and male-selective urinary retention. We are now comparing the phenotype of M₄ knockout mice with that of M₃ knockout mice, because M₂ and M₃ are the two major subtypes in smooth muscle organs. Furthermore, we have established a double knockout mouse line lacking both M₂ and M₃ and analyzing their phenotypes.

In addition, mAChRs are supposed to be important in several aspects of brain functions. These include learning and memory, drug addiction, sleep and respiratory control, and striatal function. We are investigating the role of each subtype in these functions, employing molecular biology, electrophysiology, and behavioral experiments.

Our mice are now regarded as invaluable resources in the research community and we are organizing many collaborative programs (both domestic and international) as well.

6. Role of MAP kinase signaling in synaptic plasticity

Ayako M. Watabe, Noriko Kumazawa, Thomas J. O’Dell⁹ and Toshiya Manabe:¹Department of Physiology, School of Medicine, University of California, Los Angeles

Several lines of evidence including ours have suggested that the mitogen-activated protein kinase (MAPK) signaling cascade plays a regulatory role in the induction of LTP. We therefore examined the change in synaptic transmission and plasticity in genetically manipulated mice that carry no SynGAP, a GTPase-activating protein known to interact with PSD-95 and negatively regulate MAPK signaling. The mutant mice showed a reduced level of LTP at all examined protocols and showed deficits in a hippocampus-dependent spatial learning test, which can be overcome by excess training. The molecular mechanisms underlying this LTP and learning impairment is still unclear, and the studies to identify the altered MAPK pathways in the mutant mice are now in progress.

8. Mechanisms of bidirectional synaptic modification

Ayako M. Watabe, Hideki Miwa, Noriko Kumazawa, Thomas J. O’Dell⁹, and Toshiya Manabe

a. Characterization of mGluR-dependent synaptic plasticity

Activity-dependent modification of synaptic strength plays a key role in neural development and some forms of neuronal plasticity. While much focus has been on the LTP mechanisms, not much is known for the molecular mechanisms of LTD, long-lasting suppression of synaptic strength. Recently, it has been reported that activation of the metabotropic glutamate receptor (mGluR) with the group I mGluR agonist (R,S)-3,5-dihydroxyphenylglycine (DHPG) induces LTD in the CA1 region of the hippocampus. We investigated potential roles of pre- and postsynaptic processes in the DHPG-induced LTD. DHPG-induced LTD was completely blocked when GDP-βS was delivered into postsynaptic cells, strongly suggesting that DHPG depresses synaptic transmission through a postsynaptic, G protein-mediated signaling pathway. On the other hand, the effect of DHPG was strongly modulated by experimental manipulations that altered pre synaptic calcium influx. Also, enhancing calcium influx by
prolonging action potential duration with bath applications of the potassium channel blocker 4-AP strongly reduced the effect of DHPG. Furthermore, while inhibiting both pre- and postsynaptic potassium channels with bath-applied 4-AP blocked the effects of DHPG, inhibition of postsynaptic potassium channels alone with intracellular cesium and TEA had no effect on the ability of DHPG to inhibit synaptic transmission. These results suggest that activation of postsynaptic mGluRs suppresses transmission at excitatory synapses onto CA1 pyramidal cells through presynaptic effects on transmitter release. Further physiological roles of mGluRs in synaptic transmission and activity-dependent modification of synaptic transmission are currently in progress.

b. Molecular mechanisms of metaplasticity

While certain patterns of synaptic stimulation can change synaptic strength, the degree and/or direction of the synaptic modification itself can strongly depend on the previous history of the synaptic stimulation. This effect of the stimulus history onto the plasticity, or plasticity of plasticity (metaplasticity), has been implicated from the theoretical point of view in neuronal network development, but its physiological and biochemical mechanisms are still unclear. To elucidate molecular and cellular mechanisms underlying metaplasticity, possible involvement of mGluRs and NMDA receptors and their modulation such as phosphorylation and dephosphorylation are currently investigated.
